金匱要略

A black and white photomicrograph showing a dense cellular infiltrate. The infiltrate consists primarily of small lymphocytes, interspersed with several larger, more pleomorphic lymphoid cells, some of which appear to be centroblasts or immunoblasts. There are also a few plasma cells visible. The overall pattern suggests a non-Hodgkin's lymphoma, possibly a large cell lymphoma.

This grayscale image depicts a surface with a fine, granular texture. A prominent feature is a diagonal line running from the top right towards the bottom left. This line is composed of several short, thick segments, creating a dashed effect. The overall composition is minimalist, focusing on the interplay between the organic texture of the surface and the geometric precision of the line.
